one of the first college level texts for elementary courses in non euclidean geometry this volume is geared toward students familiar with calculus topics include the fifth postulate hyperbolic plane geometry and trigonometry and elliptic plane geometry and trigonometry extensive appendixes offer background information on euclidean geometry and numerous exercises appear throughout the text reprint of the holt rinehart winston inc new york 1945 edition

in this book dr coolidge explains non euclidean geometry which consists of two geometries based on axioms closely related to

those specifying euclidean geometry as euclidean geometry lies at the intersection of metric geometry and affine geometry non euclidean geometry arises when either the metric requirement is relaxed or the parallel postulate is replaced with an alternative one in the latter case one obtains hyperbolic geometry and elliptic geometry the traditional non euclidean geometries when the metric requirement is relaxed then there are affine planes associated with the planar algebras which give rise to kinematic geometries that have also been called non euclidean geometry the essential difference between the metric geometries is the nature of parallel lines euclid's fifth postulate the parallel postulate is equivalent to playfair's postulate which states that within a two dimensional plane for any given line l and a point a which is not on l there is exactly one line through a that does not intersect l in hyperbolic geometry by contrast there are infinitely many lines through a not intersecting l while in elliptic geometry any line through a intersects l another way to describe the differences between these geometries is to consider two straight lines indefinitely extended in a two dimensional plane that are both perpendicular to a third line in euclidean geometry the lines remain at a constant distance from each other meaning that a line drawn perpendicular to one line at any point will intersect the other line and the length of the line segment joining the points of intersection remains constant and are known as parallels in hyperbolic geometry they curve away from each other increasing in distance as one moves further from the points of intersection with the common perpendicular these lines are often called ultraparallels in elliptic geometry the lines curve toward each other and intersect

examines various attempts to prove euclid's parallel postulate by the greeks arabs and renaissance mathematicians it considers forerunners and founders such as saccheri lambert legendre w bolyai gauss others includes 181 diagrams

an introduction to non euclidean geometry covers some introductory topics related to non euclidian geometry including hyperbolic and elliptic geometries this book is organized into three parts encompassing eight chapters the first part provides mathematical proofs of euclid's fifth postulate concerning the extent of a straight line and the theory of parallels the second part describes some problems in hyperbolic geometry such as cases of parallels with and without a common perpendicular this part also deals with horocycles and triangle relations the third part examines single and double elliptic geometries this book will be of great value to mathematics liberal arts and philosophy major students

there are many technical and popular accounts both in russian and in other languages of the non euclidean geometry of lobachevsky and bolyai a few of which are listed in the bibliography this geometry also called hyperbolic geometry is part of the required subject matter of many mathematics departments in universities and teachers colleges a reflection of the view that familiarity with the elements of hyperbolic geometry is a useful part of the background of future high school teachers much attention is paid to hyperbolic geometry by school mathematics clubs some mathematicians and educators concerned with reform of the high school curriculum believe that the required part of the curriculum should include elements of hyperbolic geometry and that the optional part of the curriculum should include a topic related to hyperbolic geometry in the broad interest in hyperbolic geometry is not surprising this interest has little to do with mathematical and scientific applications of hyperbolic geometry since the applications for instance in the theory of automorphic functions are rather specialized and are likely to be encountered by very few of the many students who conscientiously study and then present to examiners the definition of parallels in hyperbolic geometry and the special features of configurations of lines in the hyperbolic plane the principal reason for the interest in hyperbolic geometry is the important fact of non uniqueness of geometry of the existence of many geometric systems

the russian edition of this book appeared in 1976 on the hundred and fiftieth anniversary of the historic day of february 23 1826 when lobachevskii delivered his famous lecture on his discovery of non euclidean geometry the importance of the discovery of non euclidean geometry goes far beyond the limits of geometry itself it is safe to say that it was a turning point in the history of all mathematics the scientific revolution of the seventeenth century marked the transition from mathematics of constant magnitudes to mathematics of variable magnitudes during the seventies of the last century there occurred another scientific revolution by that time mathematicians had become familiar with the ideas of non euclidean geometry and the algebraic ideas of group and field all of which appeared at about the same time and the later ideas of set theory this gave rise to many geometries in addition to the euclidean geometry previously regarded as the only conceivable possibility to the arithmetics and algebras of many groups and fields in addition to the arithmetic and algebra of real and complex numbers and finally to new mathematical systems i e sets furnished with various structures having no classical analogues thus in the 1870 s there began a new mathematical era usually called until the middle of the twentieth century the era of modern mathematics

this book develops a self contained treatment of classical euclidean geometry through both axiomatic and analytic methods concise and well organized it prompts readers to prove a theorem yet provides them with a framework for doing so chapter topics cover neutral geometry euclidean plane geometry geometric transformations euclidean 3 space euclidean n space perimeter area and volume spherical geometry hyperbolic geometry models for plane geometries and the hyperbolic metric

non euclidean geometry is now recognized as an important branch of mathematics those who teach geometry should have some

knowledge of this subject and all who are interested in mathematics will find much to stimulate them and much for them to enjoy in the novel results and views that it presents this book is an attempt to give a simple and direct account of the non euclidean geometry and one which presupposes but little knowledge of mathematics the first three chapters assume a knowledge of only plane and solid geometry and trigonometry and the entire book can be read by one who has taken the mathematical courses commonly given in our colleges no special claim to originality can be made for what is published here the propositions have long been established and in various ways some of the proofs may be new but others as already given by writers on this subject could not be improved these have come to me chiefly through the translations of professor george bruce halsted of the university of texas i am particularly indebted to my friend arnold b chace sc d of valley falls ri with whom i have studied and discussed the subject henry p manning contents pangeometry propositions depending only on the principle of superposition propositions which are true for restricted figures the three hypotheses the hyperbolic geometry parallel lines boundary curves and surfaces and equidistant curves and surfaces trigonometrical formulæ the elliptic geometry analytic non euclidean geometry hyperbolic analytic geometry elliptic analytic geometry elliptic solid analytic geometry historical notes the axioms of geometry were formerly regarded as laws of thought which an intelligent mind could neither deny nor investigate not only were the axioms to which we have been accustomed found to agree with our experience but it was believed that we could not reason on the supposition that any of them are not true it has been shown however that it is possible to take a set of axioms wholly or in part contradicting those of euclid and build up a geometry as consistent as his we shall give the two most important non euclidean geometries 1 in these the axioms and definitions are taken as in euclid with the exception of those relating to parallel lines omitting the axiom on parallels 2 we are led to three hypotheses one of these establishes the geometry of euclid while each of the other two gives us a series of propositions both interesting and useful indeed as long as we can examine but a limited portion of the universe it is not possible to prove that the system of euclid is true rather than one of the two non euclidean geometries which we are about to describe we shall adopt an arrangement which enables us to prove first the propositions common to the three geometries then to produce a series of propositions and the trigonometrical formulæ for each of the two geometries which differ from that of euclid and by analytical methods to derive some of their most striking properties we do not propose to investigate directly the foundations of geometry nor even to point out all of the assumptions which have been made consciously or unconsciously in this study leaving undisturbed that which these geometries have in common we are free to fix our attention upon their differences by a concrete exposition it may be possible to learn more of the nature of geometry than from abstract theory alone

this is the definitive presentation of the history development and philosophical significance of non euclidean geometry as well as of the rigorous foundations for it and for elementary euclidean geometry essentially according to hilbert appropriate for liberal arts students prospective high school teachers math majors and even bright high school students the first eight chapters are mostly accessible to any educated reader the last two chapters and the two appendices contain more advanced material such as the classification of motions hyperbolic trigonometry hyperbolic constructions classification of hilbert planes and an

introduction to riemannian geometry

the discovery of hyperbolic geometry and the subsequent proof that this geometry is just as logical as euclid s had a profound influence on man s understanding of mathematics and the relation of mathematical geometry to the physical world it is now possible due in large part to axioms devised by george birkhoff to give an accurate elementary development of hyperbolic plane geometry also using the poincare model and inversive geometry the equiconsistency of hyperbolic plane geometry and euclidean plane geometry can be proved without the use of any advanced mathematics these two facts provided both the motivation and the two central themes of the present work basic hyperbolic plane geometry and the proof of its equal footing with euclidean plane geometry is presented here in terms acces sible to anyone with a good background in high school mathematics the development however is especially directed to college students who may become secondary teachers for that reason the treatment is de signed to emphasize those aspects of hyperbolic plane geometry which contribute to the skills knowledge and insights needed to teach eucli dean geometry with some mastery
